HOLOMORPHIC CORRESPONDENCES RELATED TO FINITELY GENERATED RATIONAL SEMIGROUPS

GAUTAM BHARALI AND SHRIHARI SRIDHARAN

Abstract. In this paper, we present a new technique for studying the dynamics of a finitely generated rational semigroup. Such a semigroup can be associated naturally to a certain holomorphic correspondence on $\mathbb{P}^1$. Results on the iterative dynamics of such a correspondence can now be applied to the study of the rational semigroup. We focus on an invariant measure for the aforementioned correspondence—known as the equilibrium measure. This confers some advantages over many of the known techniques for studying the dynamics of rational semigroups. We use the equilibrium measure to analyse the distribution of repelling fixed points of a finitely generated rational semigroup, and to derive a sharp bound for the Hausdorff dimension of the Julia set of such a semigroup.

1. Introduction and Statement of Results

Given two compact complex manifolds $X_1$ and $X_2$ of dimension $k$, a holomorphic correspondence from $X_1$ to $X_2$ is, in essence, a relation from $X_1$ to $X_2$ that is an analytic subset of $X_1 \times X_2$. Since two relations can be composed, one would expect to have a theory of the iterative dynamics of a holomorphic correspondence. It is to this end—which requires notions such as the degree of a correspondence, the ability to count inverse images according to multiplicity, etc.—that one has the following definition.

**Definition 1.1.** With $X_1$ and $X_2$ as above, we say that $\Gamma$ is a *holomorphic $k$-chain* in $X_1 \times X_2$ if $\Gamma$ is a formal linear combination of the form

$$\Gamma = \sum_{j=1}^{N} m_j \Gamma_j,$$

where the $m_j$’s are positive integers and $\Gamma_1, \ldots, \Gamma_N$ are distinct irreducible complex-analytic subvarieties of $X_1 \times X_2$ of pure dimension $k$. Let $\pi_i$ denote the projection onto $X_i$, $i = 1, 2$. We say that $\Gamma$ is a *holomorphic correspondence of $X_1$ onto $X_2$* if

a) for each $\Gamma_j$ in (1.1), $\pi_1|_{\Gamma_j}$ and $\pi_2|_{\Gamma_j}$ are surjective;

b) for each $x \in X_1$ and $y \in X_2$, $(\pi_1^{-1}(x) \cap \Gamma_j)$ and $(\pi_2^{-1}(y) \cap \Gamma_j)$ are finite sets for each $j$.

When $X_1$ and $X_2$ are compact Riemann surfaces, the condition (b) above holds true automatically, owing to holomorphicity and dimension. A holomorphic correspondence $\Gamma$ determines a set-valued function, which we denote by $F_{\Gamma}$, as follows:

$$X_1 \ni A \mapsto \bigcup_{j=1}^{N} \pi_2\left(\pi_1^{-1}(A) \cap \Gamma_j\right).$$

We will denote $F_{\Gamma}(\{x\})$ by $F_{\Gamma}(x)$.

Key words and phrases. Equilibrium measure, Hausdorff dimension, repelling fixed points.

The first author is supported in part by a Swarnajayanti Fellowship (Grant no. DST/SJF/MSA-02/2013-14) and by a UGC Centre for Advanced Study grant.
This is the first of several articles that will use correspondences to deduce new information on the dynamics of finitely generated rational semigroups and revisit previously studied phenomena under *weaker assumptions* than those stated in the literature. (One precise, quantitative reason why correspondences would confer an advantage over current techniques in studying rational semigroups is discussed in Remark 4.6.)

A *rational semigroup* is a subsemigroup of $\text{Hol}(\mathbb{P}^1;\mathbb{P}^1)$ — the semigroup with respect to composition of holomorphic endomorphisms of $\mathbb{P}^1$ — containing no constant functions. The study of dynamics of rational semigroups was initiated by Hinkkanen and Martin [8, 9, 10], and a lot is known by now about such dynamical systems. The aim of this work is to learn more about a finitely generated rational semigroup by associating to it a natural holomorphic correspondence and studying the dynamics of the latter.

**Definition 1.2.** Let $S$ be a finitely generated rational semigroup and let $\mathcal{G} = \{g_1, \ldots, g_N\}$ be a set of generators of $S$, i.e., $S = \langle g_1, \ldots, g_N \rangle$. We call the holomorphic 1-chain in $\mathbb{P}^1 \times \mathbb{P}^1$

$$G_{\mathcal{G}} := \sum_{1 \leq j \leq N} \text{graph}(g_j) \quad (1.2)$$

the *holomorphic correspondence associated to $(S, \mathcal{G})$*. We shall denote the set-valued function determined by $G_{\mathcal{G}}$ by $F_{\mathcal{G}}$.

$F_{\mathcal{G}}$ is a useful book-keeping device if one is interested in the statistics of the $S$-orbits $S \cdot x$, $x \in \mathbb{P}^1$. We shall give a formal definition of the composition of two correspondences $G_1$ and $G_2$ in Section 2, but we note here that the irreducible components of $G_2 \circ G_1$ are precisely those of the relation obtained by composing the relations $G_2$ and $G_1$. Thus:

$$S \cdot x = \bigcup_{n \in \mathbb{N}} F_{\mathcal{G}}^n(x)$$

and the finite unions $\bigcup_{0 \leq n \leq M} F_{\mathcal{G}}^n(x)$ give an exhaustion of $S \cdot x$. Here, $F_{\mathcal{G}}^n$ is the set-valued map determined by the $n$-fold iterate of $G_{\mathcal{G}}$.

One can construct useful invariant measures — which are analogous to the constructions of Brolin [3] or Lyubich [11] for rational maps — for holomorphic correspondences. Definition 1.2 provides a bridge between such a measure and the study of a finitely generated semigroup. In our case, we wish to exploit a measure constructed by Dinh and Sibony [5]. Suppose $X$ is a compact Riemann surface, and $\Gamma$ a holomorphic correspondence of $X$ onto itself. Let $d_1(\Gamma)$ be the generic number of inverse images of $\Gamma$ and let $d_0(\Gamma)$ be the generic number of forward images, both counted according to multiplicity (see Section 2). Dinh–Sibony show that regular Borel measures can be pulled back under a correspondence: for such a measure $\mu$, denote the pull-back by $F_{\Gamma}^* \mu$ (refer to [5, Section 2.4] for details). One of the main results of [5], applied to the setting of compact Riemann surfaces, states that when $d_1(\Gamma) > d_0(\Gamma)$, there exist a polar set $E \subset X$ and a regular Borel probability measure $\mu_\Gamma$ such that

$$\frac{1}{d_1(\Gamma)^n} F_{\Gamma \circ \mu}(\delta_x) \overset{\text{weak}^*}{\longrightarrow} \mu_\Gamma \text{ as } n \to \infty, \quad \forall x \in X \setminus E. \quad (1.3)$$

Following Dinh–Sibony, we shall call the above measure the *equilibrium measure for the correspondence $\Gamma$*. We must point out here that, under certain constraints on the generating sets $\mathcal{G}$ of a finitely generated rational semigroup $S$, the measure $\mu_\Gamma$ for the correspondence (1.2) was discovered by Boyd [1] — albeit not in the context represented by (1.3). Boyd’s construction requires $S$ to be such that there is a set of generators $\mathcal{G} = \{g_1, \ldots, g_N\}$ such that $\deg(g_j) \geq 2 \ \forall j = 1, \ldots, N$. This is necessitated by certain expansivity considerations;
Then, for the sequence of measures $\mu_{\Psi}$, denote the equilibrium measure for the correspondence $\Psi$ be a set of generators. Assume that $\deg(g_j) \geq 2$ for at least one $j$, $1 \leq j \leq N$. 

Let $\Psi_j$ denote the largest open subset of $P$.

Theorem 1.4. Let $S$ be a finitely generated rational semigroup containing at least one element of degree at least 2. Then the set of all repelling fixed points of all the elements of $S$ is dense in $J(S)$. 

Thus repelling fixed points are a significant feature of the dynamics of a rational semigroup. This raises the question: what is the distribution of these fixed points in $J(S)$? To make this question precise, we consider a finitely generated semigroup $S$. Fixing a set of generators $\Psi = \{g_1, \ldots, g_N\}$, a word will refer to any composition $g_m \circ \cdots \circ g_2 \circ g_1$, $m \in \mathbb{Z}_+$ and $j_1, \ldots, j_m \in \{1, \ldots, N\}$. For a word $w$, the expression $|w|_{\Psi} = m$ is the shorthand for the following implication:

$$|w|_{\Psi} = m \Rightarrow \exists j_1, \ldots, j_m \in \{1, \ldots, N\} \text{ such that } w = g_{j_m} \circ \cdots \circ g_{j_1}.$$ 

A more precise form of the above question is:

**Question.** Let $R(n; \Psi)^\bullet$ be the list of repelling fixed points, repeated according to multiplicity, of each of the words $w \in S$ given by $|w|_{\Psi} = n$, and let $E$ be a Borel subset of $J(S)$. What fraction of $R(n; \Psi)^\bullet$ is contained in $E$ for $n$ large?

In view of (1.4), for $S$ as in Result 1.3 and finitely generated: fixing a generating set $\Psi$, the equilibrium measure for the correspondence associated to $(S, \Psi)$—denote it by $\mu_{\Psi}$—exists (see subsection 4.1). The measure $\mu_{\Psi}$ provides the answer to our question.

**Theorem 1.4.** Let $S$ be a finitely generated rational semigroup and let $\Psi = \{g_1, \ldots, g_N\}$ be a set of generators. Assume that $\deg(g_j) \geq 2$ for at least one $j$, $1 \leq j \leq N$. Let $\mu_{\Psi}$ denote the equilibrium measure for the correspondence $\Gamma_{\Psi}$ associated to $(S, \Psi)$. Write

$$D := d_1(\Gamma_{\Psi}) = \sum_{1 \leq j \leq N} \deg(g_j).$$

Then, for the sequence of measures $\{\mu_n\}$, $\mu_n$ as defined below, we have:

$$\mu_n := \frac{1}{D^n} \sum_{x \in R(n; \Psi)^\bullet} \delta_x \overset{\text{weak}^*}{\rightarrow} \mu_{\Psi} \text{ as } n \to \infty. \quad (1.5)$$

**Remark.** We must note that $\mu_n$ is not, in general, of mass 1. But it is not hard to show that $\sharp R(n; \Psi)^\bullet \leq D^n + N^n$, whence, for large $n$, $\mu_n(E)$ does give a very good estimate of the fraction on $R(n; \Psi)^\bullet$ contained in $E$, for $E$ as in the question above.

The earliest investigations into the invariant-measure aspects of rational semigroups were undertaken by Sumi [14, 16]—following the perspectives introduced by Sullivan [13].

see [1, Sections 3 & 6]. One of the advantages of using correspondences is that one sees — with considerable clarity — that the condition

$$d_1(\Gamma_{\Psi}) > d_0(\Gamma_{\Psi}), \quad \text{equivalently} \quad \sum_{1 \leq j \leq N} \deg(g_j) > N, \quad (1.4)$$

suffices to have a very useful quantitative account of the expanding features of $S$—see Lemma 3.3 for details. Now, (1.4) is also the condition under which we have the convergence (1.3). Thus, one has the analogue of Boyd’s measure for a finitely generated rational semigroup $(S, \Psi)$ such that $\deg(g_j) \geq 2$ for at least one $j$, $1 \leq j \leq N$.

Now, for any rational semigroup $S$, recall that the Fatou set of $S$, denoted by $F(S)$, is the largest open subset of $\mathbb{P}^1$ on which $S$ is a normal family, and that the Julia set of $S$, denoted by $J(S)$, is defined as:

$$J(S) := \mathbb{P}^1 \setminus F(S).$$

Also recall:

**Result 1.3** (Hinkkanen–Martin, [8]). Let $S$ be a rational semigroup containing at least one element of degree at least 2. Then the set of all repelling fixed points of all the elements of $S$ is dense in $J(S)$.

The earliest investigations into the invariant-measure aspects of rational semigroups were undertaken by Sumi [14, 16]—following the perspectives introduced by Sullivan [13].
For a finitely-generated rational semigroup $S$, he defined $\delta$-conformal measures and $\delta$-subconformal measures in analogy with the concepts in [13]. He showed that under certain restrictions on $S$, the Hausdorff dimension of $J(S)$ is the unique number $\delta$ such that a $\delta$-conformal measure for $S$ exists. These results give a connection between two very different aspects of the dynamics of $S$, but they do not yield explicit estimates for the Hausdorff dimension of $J(S)$.

Working with the equilibrium measure $\mu$ and the use of the formalism of correspondences gives effective estimates. Our second theorem illustrates the claim that the use of correspondences allows us to study aspects of $J(S)$ under weaker assumptions on $S$ than those assumed in the literature (and with estimates that are sharp). To elaborate further, we first state our next result, and then compare it with what is currently known.

**Theorem 1.6.** Let $S$ be a finitely generated rational semigroup and let $\mathcal{G} = \{g_1, \ldots, g_N\}$ be a set of generators. Assume that $\deg(g_j) \geq 2$ for at least one $j$, $1 \leq j \leq N$, and that, for each $j$, $g_j$ has no critical points in $J(S)$. Fix a system of global projective coordinates $[z_0 : z_1]$ such that $J(S) \subset \{(z_0 : z_1) \in \mathbb{P}^1 : z_0 \neq 0\}$ and $g_j(J(S)) \subset \{(z_0 : z_1) \in \mathbb{P}^1 : z_0 \neq 0\}$, $1 \leq j \leq N$. Let $G_j : \Omega \to \mathbb{C}$, $\Omega$ a sufficiently small neighbourhood of $J(S)$, be such that $1$ relative to the above coordinates $\leq j$ for each $J$ correspondences allows us to study aspects of $J(S)$ under weaker assumptions on $S$ than those assumed in the literature (and with estimates that are sharp). To elaborate further, we first state our next result, and then compare it with what is currently known.

Moreover, this inequality is sharp in that, for each $N \in \mathbb{Z}_+$, there is a semigroup $S_N$ with $N$ generators, and with the above properties, for which (1.6) holds true as an equality.

We use $\dim_H$ to denote the Hausdorff dimension. In view of Result 1.3, (1.6) tells us that $\dim_H(J(S)) > 0$ for $S$ having the above-stated properties.

We must mention here that this is not the only work wherein one uses an auxiliary dynamical system — the iteration of $\Gamma_\mathcal{G}$ in our case — to study finitely generated rational semigroups. In [15], Sumi studies a certain class of rational semigroups by associating to them a natural skew-product map. This is the class of finitely generated rational semigroups wherein each $S$ admits a generating set $\mathcal{G} = \{g_1, \ldots, g_N\}$ such that:

$(\ast)$ \textit{EITHER} $\deg(g_j) \geq 2 \ \forall j = 1, \ldots, N,$

\textit{OR} $\deg(g_j) \geq 2$ for at least one $j$, $1 \leq j \leq N$ and $F(H) \supset J(S),$

where $H$ is the rational semigroup $H = \{f^{-1} : f \in S$ and $\deg(f) = 1\}$.

Several of the works cited above — also see Sumi–Urbański [18, 19] — provide some estimates for $\dim_H(J(S))$ under various conditions on $S$. In most of these works, lower bounds are provided for semigroups that are expanding (see [17, Section 1] for a definition) and satisfy one of several forms of an open set condition. Unless $J(S)$ has fewer than 3 points, all forms of the open set condition imply, given that $S = \langle g_1, g_2, \ldots, g_N \rangle$, the following condition (see [17, Lemma 5.2], for instance):

$\text{(Separation Condition)} \quad g_j^{-1}(J(S)) \cap g_k^{-1}(J(S)) = \emptyset$ \quad $j \neq k.$ \quad (1.7)

In summary, the two distinct types of conditions on the semigroup $S$, provided at least one of its generators is of degree $\geq 2$, under which the aforementioned works provide a lower bound on $\dim_H(J(S))$ are:

- $S$ satisfies the separation condition $(1.7)$ \textit{AND} Condition $(\ast)$ above;
• $S$ satisfies some form of an open set condition AND is expanding.

The proof of Theorem 1.6 involves studying the iterates of the correspondence $\Gamma_g$ associated to $(S, \mathcal{G})$. The utility of this is that it has no need for a condition such as (1.7). As for the condition that $S$ be expanding (in the sense of [14, 17]): it follows from the definition — see [17, Section 1], for instance — that there exist constants $C > 0$ and $\lambda > 1$ such that, with $(S, \mathcal{G})$ as in Definition 1.2:

$$\text{for each word } w, \ |w|_g = m \Rightarrow \inf_{x \in J(S)} \|w'(x)\|_{\text{sph}} \geq C\lambda^m,$$

where we use $\| \cdot \|_{\text{sph}}$ to denote the magnitude of the derivative relative to the spherical metric. Thus, the case wherein $S$ is expanding — which is addressed in [17, 18, 19] — is subsumed by our condition in Theorem 1.6. Moreover, our bound for $\dim H(J(S))$ is sharp.

2. Technical Preliminaries

In this section, we shall define and elaborate upon a couple of concepts that were mentioned merely in passing in Section 1. We begin with a note on language: given a complex manifold $X$, the phrase holomorphic correspondence on $X$ will refer to any holomorphic correspondence of $X$ onto itself.

2.1. The composition of two holomorphic correspondences. Although the focus of this work is correspondences of the form (1.2), we shall not restrict ourselves to these forms in the following series of definitions. This is because — with $X_1 = X_2 = X$ as in Section 1 and $\Gamma$ a correspondence of the form (1.1) — it will be crucial (especially in the proof of Theorem 1.6) to understand the need/role of the coefficients $m_j$.

Observe that $\Gamma$ gives an obvious relation on $X$: we shall denote it as $|\Gamma|$, where, assuming the representation (1.1),

$$|\Gamma| : = \bigcup_{j=1}^N \Gamma_j,$$

I.e., $|\Gamma|$ is just the set underlying the object $\Gamma$. Now consider two holomorphic correspondences, determined by the $k$-chains

$$\Gamma^1 = \sum_{j=1}^{N_1} m_{1,j} \Gamma_{1,j}, \quad \Gamma^2 = \sum_{j=1}^{N_2} m_{2,j} \Gamma_{2,j},$$

in $X \times X$. The set underlying the composition $\Gamma^2 \circ \Gamma^1$ is, in fact, the classical composition of the relation $|\Gamma^2|$ with the relation $|\Gamma^1|$. If we denote the classical composition by $\star$, then recall that

$$|\Gamma^2| \star |\Gamma^1| : = \{(x, z) \in X \times X : \exists y \in X \text{ s.t. } (x, y) \in |\Gamma^1|, (y, z) \in |\Gamma^2|\}. \quad (2.1)$$

However, the object $\Gamma^2 \circ \Gamma^1$ must include additional numerical data. To determine these, we first note that the $k$-chains $\Gamma_1$, $\Gamma_2$ have the alternative representations

$$\Gamma^1 = \sum_{1 \leq j \leq L_1} \Gamma_{1,j}^\prime, \quad \Gamma^2 = \sum_{1 \leq j \leq L_2} \Gamma_{2,j}^\prime,$$

where the primed sums indicate that the irreducible subvarieties $\Gamma_{s,j}^\prime$, $j = 1, \ldots, L_s$, are not necessarily distinct and are repeated according to the coefficients $m_{s,j}$.

Firstly, the $k$-chain $\Gamma_{2,i}^\prime \circ \Gamma_{1,j}^\prime$ is determined by the following two conditions:

$$|\Gamma_{2,i}^\prime \circ \Gamma_{1,j}^\prime| = \{(x, z) \in X \times X : \exists y \in X \text{ s.t. } (x, y) \in \Gamma_{1,j}^\prime, (y, z) \in \Gamma_{2,i}^\prime\}, \quad (2.3)$$

$$\Gamma_{2,i}^\prime \circ \Gamma_{1,j}^\prime \equiv \sum_{1 \leq s \leq N(j,i)} \nu_{s,j} Y_{s,j},$$
where the $Y_{s,jl}$'s are the distinct irreducible components of the subvariety on the right-hand side of (2.3) (which is the relation $|\Gamma_{2,l}^*| \ast |\Gamma_{1,j}^*|$), and $\nu_{s,jl} \in \mathbb{Z}_+$ is the generic number $y$'s as $(x,z)$ varies through $Y_{s,jl}$ for which the membership conditions on the right-hand side of (2.3) are satisfied. We now define:

$$\Gamma^2 \circ \Gamma^1 := \sum_{1 \leq j \leq L_1} \sum_{1 \leq l \leq L_2} \Gamma_{2,l}^* \circ \Gamma_{1,j}^*.$$ (2.4)

If $\Gamma^1$ and $\Gamma^2$ are two holomorphic correspondences on $X$, then it is well known that so is $\Gamma^2 \circ \Gamma^1$. This is especially obvious in the case of two correspondences of the form (1.2). Furthermore, correspondences of this form reveal why it is desirable that the coefficients $m_1, \ldots, m_N$ form a part of the data defining a correspondence in the sense of Definition 1.1. To see this, consider a rational semigroup $S = \langle g_1, \ldots, g_N \rangle$ that is not freely generated. Suppose, for example, there exists a relation

$$g_2 \circ g_1 = g_\mu \circ g_\nu, \quad 1 \leq \mu, \nu \leq N, \mu \neq 2, \text{ and } \nu \neq 1.$$ 

With $\Gamma_{g_2}^* \circ \Gamma_{g_1}^*$ being the correspondence associated to $(S, g)$, $g = \{g_1, \ldots, g_N\}$, we have by definition:

$$\Gamma_{g_2}^* \circ \Gamma_{g_1}^* = \sum_{1 \leq j, l \leq N \nu} \text{graph}(g_l \circ g_j).$$ (2.5)

Note that, due to the aforementioned relation, the irreducible variety $\text{graph}(g_2 \circ g_1)$ occurs with multiplicity at least two in the above expression. We shall soon see that we do want to keep a count of this multiplicity. This phenomenon illustrates why one requires the coefficients $m_1, \ldots, m_N$, in the sense of (1.1), to form a part of the data defining a holomorphic correspondence. It is the presence of these multiplicity data that necessitates a definition that calls for more than merely composing $|\Gamma^1|$ and $|\Gamma^2|$ as relations.

### 2.2. The numbers $d_1(\Gamma)$ and $d_0(\Gamma)$

The topological degree of a holomorphic correspondence is the generic number of preimages of a point, counted according to multiplicity. To be more precise, we first recall that, with the representation (1.1) for $\Gamma$, it is classical that there is a Zariski-open set $\Omega \subset X_2$ such that $(\pi_2^{-1}(\Omega) \cap \Gamma_j, \Omega, \pi_2)$ is a $\Delta_j$-sheeted holomorphic covering for some $\Delta_j \in \mathbb{Z}_+$, $j = 1, \ldots, N$. The topological degree of $\Gamma$ is defined as

$$\deg_{\text{top}}(\Gamma) := \sum_{j=1}^{N} m_j \Delta_j.$$ (2.6)

When $\dim_{\mathbb{C}}(X_1) = \dim_{\mathbb{C}}(X_2) = 1$, $\deg_{\text{top}}(\Gamma)$ is abbreviated to $d_1(\Gamma)$ (this notation is meant to evoke the dynamical degrees $d_i(\Gamma)$ of $\Gamma$, $i = 0, 1, \ldots, \dim_{\mathbb{C}}(X_2)$, which were defined in [5] but whose definitions are not essential to understand the results herein).

Let $X$ be a compact Riemann surface and let $\Gamma$ be a holomorphic correspondence on $X$. Keeping in mind the issue of multiplicity discussed in the previous sub-section, we find that (2.6) is the “correct” way to count the number of pre-images of generic points: i.e., we get the following simple formula (here $\Gamma^{\circ n}$ denotes the $n$-fold iterated composition of $\Gamma$).

**Proposition 2.1.** Let $X$ be a compact Riemann surface and let $\Gamma$ be a holomorphic correspondence on $X$. Then $d_1(\Gamma^{\circ n}) = d_1(\Gamma)^n \forall n \in \mathbb{Z}_+.$

Essentially the same reasoning used for holomorphic maps applies even when $\Gamma$ is not the graph of a map. Let $w \in X$ be a generic point in the sense of the discussion preceding (2.6). Since $\Gamma$ has no irreducible components of the form $\{a\} \times X$ or $X \times \{a\}$,
For $X_1, X_2$ and $\Gamma$ as in Section 1, the adjoint of $\Gamma$ is the correspondence (assuming, once again, the representation (1.1) for $\Gamma$)

$$\Gamma^\dagger := \sum_{j=1}^{N} m_j \Gamma^\dagger_j,$$

where $\Gamma^\dagger_j := \{(y, x) \in X_2 \times X_1 : (x, y) \in \Gamma_j\}$.

When $\dim_C(X_1) = \dim_C(X_2) = 1$, define $d_0(\Gamma) := d_1(\Gamma^\dagger)$.

3. Essential notations and lemmas

This section is dedicated to various lemmas needed to prove Theorems 1.4 and 1.6.

We will need an area-diameter comparison for $P^1$-valued maps that are holomorphic on the open unit disc $D \subset \mathbb{C}$, which is due to Briend and Duval [2]. In what follows, $D(a; r)$ is the open disc of radius $r$ centered at $a \in \mathbb{C}$; for a set $A \subset P^1$, its diameter $\text{diam}(A)$ is with respect to the spherical distance; and, for any of the maps $\phi$ appearing in the following result,

$$\text{area}(\phi(\Omega)) := \int_{\Omega} \phi^* \omega_{FS},$$

where $\Omega$ is any open subset of $D$, and $\omega_{FS}$ denotes the normalised Fubini–Study form on $P^1$.

Result 3.1 (paraphrasing Lemme 3.6 of [4]). There exists a constant $\delta_0 > 0$ such that for any injective holomorphic map $\phi : D \to P^1$ satisfying $\text{area}(\phi(D)) \leq \delta_0$, the following holds: given any $r \in (0, 1)$, there exists a constant $c(r) > 0$ — which is independent of $\phi$ — such that

$$\text{diam}(\phi(D(0; r))) \leq c(r) \sqrt{\text{area}(\phi(D(0; r)))}.$$ 

Remark 3.2. Briend–Duval give a more general form of the above result, for $P^k$-valued maps, in [2]. However, we shall use the formulation given in [4, Lemme 3.6] by Dinh.

As in subsection 2.1, we shall, for a part of this section, set up our notation and constructions for general holomorphic correspondences on a compact Riemann surface $X$ — even though we shall eventually discuss correspondences of the form (1.2). This allows us to better relate what we need here to the notation in the works to which we need to refer.

If $\omega_X$ is a Kähler form on $X$ with $\int_X \omega_X = 1$, it follows from the change-of-variables formula for branched coverings that for a holomorphic correspondence $\Gamma$ on $X$:

$$d_1(\Gamma) = \sum_{j=1}^{N} m_j \int_{\text{reg}(\Gamma_j)} (\pi_2|_{\Gamma_j})^* \omega_X \quad \text{and} \quad d_0(\Gamma) = \sum_{j=1}^{N} m_j \int_{\text{reg}(\Gamma_j)} (\pi_1|_{\Gamma_j})^* \omega_X; \quad (3.1)$$

also see [5, equation (3.1)] together with [5, Section 3.5].

We have almost all the ingredients needed to state a lemma that will play a key role in the proof of Theorem 1.4. To this end, we need to fix a couple of basic notions: firstly, given a non-empty open set $U \subset X$, we will call a map $\gamma : U \to X$ a regular inverse branch of $\Gamma$ if there exists some $j$, $1 \leq j \leq N$, and some irreducible component $C$ of $\pi_2^{-1}(U) \cap \Gamma_j$ — viewed as an analytic subset of $X \times U$ — such that
abbreviate the set $U$ function of list the $\Gamma$ be the representations, in the form (1.1), of the correspondences distinction between lists and sets. These are the notational rules that we shall follow:

- A collection denoted by $A^*$ will represent a list; the objects in $A^*$ will be repeated according to multiplicity. Also, $A$ will denote the set underlying $A^*$.
- The notation $\sharp(A^*)$ will denote the number of objects in $A^*$, counted according to multiplicity. Cardinality will be denoted by $\text{Card}$.

**Lemma 3.3.** Let $\{\Gamma_n\}$ be a sequence of holomorphic correspondences on $\mathbb{P}^1$ such that, for some $\varepsilon \in (0, 1)$, and for some open set $U \subseteq \mathbb{P}^1$ biholomorphic to $\mathbb{D}$, we have that $U$ admits at least $(1 - \varepsilon/2)d_1(\Gamma_n)$ regular inverse branches of $\Gamma_n$, counting according to multiplicity, for each $n \in \mathbb{Z}_+$. Furthermore, assume that $\lim_{n \to \infty} d_0(\Gamma_n)/d_1(\Gamma_n) = 0$. Then:

a) There exists a constant $K_\varepsilon > 0$ such that for all $n \in \mathbb{Z}_+$ and for at least $(1 - \varepsilon)d_1(\Gamma_n)$ of the aforementioned inverse branches of $\Gamma_n$, the areas of the images of $U$ are at most $K_\varepsilon d_0(\Gamma_n)/d_1(\Gamma_n)$.

b) Fix $W \in U$. If $n^\gamma$ is one of the inverse branches of $\Gamma_n$ mentioned in (a), then

$$\text{diam}(n^\gamma(W)) = O\left(\sqrt{d_0(\Gamma_n)/d_1(\Gamma_n)}\right) \text{ as } n \to \infty.$$ 

**Remark 3.4.** The above lemma may be viewed as a version—suitably reformulated for sequences of correspondences—of a lemma in [2, Section 1]. Areas and diameters occurring in the above lemma are as described prior to the statement of Result 3.1.

**The proof of Lemma 3.3.** Let

$$\sum_{j=1}^{N(n)} m_{n,j}\Gamma_{n,j}, \quad n = 1, 2, 3, \ldots$$

be the representations, in the form (1.1), of the correspondences $\Gamma_n$, and let $\mathcal{F}(n)^\ast$ denote the list of inverse branches of $\Gamma_n$ given by our hypothesis. Then (in the following, we abbreviate the set $\{(z, w) : z = n^\gamma(w), w \in U\}$ as $\text{gr}(n^\gamma)$, and write $\chi_U$ for the characteristic function of $U$)

$$\sum_{n^\gamma \in \mathcal{F}(n)^\ast} \text{area}(n^\gamma(U)) = \sum_{n^\gamma \in \mathcal{F}(n)^\ast} \int_U n^\gamma^* \omega_{FS}$$

$$= \sum_{n^\gamma \in \mathcal{F}(n)^\ast} \int_{\text{gr}(n^\gamma)^\ast} \left(\pi_2|_{\text{gr}(n^\gamma)}\right)^* \left(\pi_1|_{\text{gr}(n^\gamma)}\right)^* \omega_{FS}$$

$$\leq \sum_{1 \leq j \leq N(n)} m_{n,j} \int_{\text{reg}(\Gamma_{n,j})} \left(\pi_2|_{\Gamma_j}\right)^* \chi_U \left(\pi_1|_{\Gamma_j}\right)^* \omega_{FS}$$

$$\leq \sum_{1 \leq j \leq N(n)} m_{n,j} \int_{\text{reg}(\Gamma_{n,j})} \left(\pi_1|_{\Gamma_j}\right)^* \omega_{FS} = d_0(\Gamma_n). \quad (3.2)$$

Here, the first inequality above is due to the fact that the union of the graphs of every $n^\gamma \in \mathcal{F}(n)$ is a subset of $(X \times U) \cap |\Gamma_n|$. The final equality above is one of the identities in (3.1). Let $M(n)$ denote the number of branches $n^\gamma \in \mathcal{F}(n)^\ast$ such that

$$\text{area}(n^\gamma(U)) \geq 2\varepsilon^{-1} d_0(\Gamma_n)/d_1(\Gamma_n).$$
By (3.2), we have
\[
\frac{2}{\varepsilon} \frac{d_0(\Gamma_n)}{d_1(\Gamma_n)} M(n) \leq d_0(\Gamma_n),
\]
from which (a) follows, with \( K_\varepsilon = 2\varepsilon^{-1} \).

Let us fix \( W \subset U \) and fix a Riemann mapping \( \psi : \mathbb{D} \to U \). Let \( \mathcal{F}(n)^* \) denote the list of inverse branches of \( \Gamma_n \) given by (a), and let \( \delta_0 \) be as given by Result 3.1. By the area bound given by (a) and by our assumption on \( d_0(\Gamma_n)/d_1(\Gamma_n) \), there exists a number \( N_\varepsilon \in \mathbb{N} \) such that
\[
\text{area}(n^\gamma \circ \psi(\mathbb{D})) \leq \delta_0 \quad \forall n^\gamma \in \mathcal{F}(n) \text{ and } \forall n \geq N_\varepsilon.
\]

Let \( r \in (0,1) \) be such that \( \psi^{-1}(W) \subset D(0;r) \). By the above inequality, we are in a position to apply Result 3.1 to \( n^\gamma \circ \psi \) for each \( n^\gamma \in \mathcal{F}(n) \) for \( n \) sufficiently large. With \( c(r) \) as given by Result 3.1, we get
\[
\text{diam}(n^\gamma(W)) \leq c(r)\sqrt{K_\varepsilon\sqrt{d_0(\Gamma_n)/d_1(\Gamma_n)}} \quad \forall n^\gamma \in \mathcal{F}(n) \text{ and } \forall n \geq N_\varepsilon,
\]
which establishes (b). \( \Box \)

We now turn to finitely generated rational semigroups. Let \( \mathcal{G} = \{g_1, \ldots, g_N\} \) be a set of generators of such a semigroup, and let \( \Gamma_{\mathcal{G}} \) be the associated holomorphic correspondence. The latter is a special case of correspondences of the form
\[
\Gamma = \sum_{1 \leq j \leq N} \text{graph}(g_j),
\] (3.3)
where each \( g_j \) is a rational map, \( g_1, \ldots, g_N \) not necessarily distinct. We call a point in \( \mathbb{P}^1 \) a critical value of \( \Gamma \) if it is a critical value of some \( g_j, 1 \leq j \leq N \). We write
\[
\text{crit}(\Gamma) := \text{the set of all critical values of } \Gamma.
\]

We now turn to finitely generated rational semigroups. Let \( \mathcal{G} = \{g_1, \ldots, g_N\} \) be a set of generators of such a semigroup, and let \( \Gamma_{\mathcal{G}} \) be the associated holomorphic correspondence. The latter is a special case of correspondences of the form
\[
\Gamma = \sum_{1 \leq j \leq N} \text{graph}(g_j),
\] (3.3)
where each \( g_j \) is a rational map, \( g_1, \ldots, g_N \) not necessarily distinct. We call a point in \( \mathbb{P}^1 \) a critical value of \( \Gamma \) if it is a critical value of some \( g_j, 1 \leq j \leq N \). We write
\[
\text{crit}(\Gamma) := \text{the set of all critical values of } \Gamma.
\]

We define \( \text{crit}(\Gamma^n) \) in an analogous way. Finally, write
\[
C_n := \bigcup_{j=1}^n \text{crit}(\Gamma^{nj}).
\]

We can now state:

**Lemma 3.5.** Let \( \Gamma \) be a holomorphic correspondence of the form (3.3). Let \( U \subsetneq \mathbb{P}^1 \) be a simply connected open set and assume that \( U \cap C_l = \emptyset \) for some \( l \in \mathbb{N} \). Then, counting according to multiplicity, \( \Gamma^n \) admits at least
\[
d_1(\Gamma)^n \left[ 1 - \left( \frac{N}{d_1(\Gamma)} \right)^l \tau(N + 1) \right]
\]
regular inverse branches, where \( \tau = \text{Card}(C_1) \).

**Proof.** A substantial part of the proof of the above statement occurs at the beginning of Section 6.8 of the work of Boyd discussed in Section 1: i.e., in [1]. Write
\[
\sigma_n := \text{the number, counting according to multiplicity, of regular inverse branches of } \Gamma^n.
\]
Since \( d_1(\Gamma) \) is the generic number of inverse images under \( \Gamma \), counted according to multiplicity, the result is obvious for \( n \leq l \). The following inequality obtained by Boyd — by a
variation of the argument by Lyubich in [11, Proposition 4] — does not require his condition that $\text{deg}(g_j) \geq 2$ for every $j = 1, \ldots, N$:

$$\sigma_n \geq d_1(\Gamma)^n - \tau N^l \sum_{j=1}^{n-l} d_1(\Gamma)^j N^{n-l-j}, \quad n \geq l + 1.$$ 

We are done if $\text{deg}(g_j) = 1$ for each $j = 1, \ldots, N$. Thus, assume that $\text{deg}(g_j) \geq 2$ for some $j = 1, \ldots, N$. Then for the right-hand side of the above inequality, we have

$$d_1(\Gamma)^n - \tau N^l \sum_{j=1}^{n-l} d_1(\Gamma)^j N^{n-l-j} \geq d_1(\Gamma)^n \left[ 1 - \left( \frac{N}{d_1(\Gamma)} \right)^l \frac{\tau}{1 - N/d_1(\Gamma)} \right]$$

$$\geq d_1(\Gamma)^n \left[ 1 - \left( \frac{N}{d_1(\Gamma)} \right)^l \tau(N + 1) \right].$$

□

4. The proof of Theorem 1.4

This section is divided into two subsections. Before we give the proof of Theorem 1.4, we must take a closer look at the equilibrium measure of Dinh–Sibony. This will be the focus of the first subsection. In that subsection, we shall also present a lemma involving the equilibrium measure, which will be needed in our proof of Theorem 1.4.

4.1. More about the equilibrium measure of Dinh–Sibony. Since some readers might not be familiar with the results of [5] — which address a much more general (and multi-dimensional) set-up than ours — we shall not merely refer the reader to the relevant sections of [5]. We shall paraphrase the relevant results, adapting them to the following objects: the normalised Fubini–Study form $\omega_{FS}$ on $\mathbb{P}^1$, and to holomorphic correspondences on $\mathbb{P}^1$. We will need two results to establish (1.3) above, which is the key fact about the equilibrium measure.

Result 4.1 (Théorème 5.1 of [5] paraphrased for correspondences on $\mathbb{P}^1$). Let $\Gamma_n, n \in \mathbb{Z}_+$, be holomorphic correspondences on $\mathbb{P}^1$. Suppose that the series

$$\sum_{n \in \mathbb{Z}_+} (d_0(\Gamma_1)/d_1(\Gamma_1)) \cdots (d_0(\Gamma_n)/d_1(\Gamma_n))$$

converges. Then, there exists a regular Borel probability measure $\mu$ such that

$$d_1(\Gamma_1)^{-1} \cdots d_1(\Gamma_n)^{-1} F_{\Gamma_n \circ \cdots \circ \Gamma_1}^*(\omega_{FS}) \xrightarrow{\text{weak}^*} \mu$$

as measures, as $n \to \infty$. The measure $\mu$ places no mass on polar sets.

Result 4.2 (a part of Théorème 1.2 of [5] paraphrased for correspondences on $\mathbb{P}^1$). Let $\Gamma_n, n \in \mathbb{Z}_+$, be holomorphic correspondences on $\mathbb{P}^1$. Suppose $\sum_{n \in \mathbb{Z}_+} d_0(\Gamma_n)/d_1(\Gamma_n)$ converges. Then, there exists a polar set $\mathcal{E} \subsetneq \mathbb{P}^1$ such that for any $w \in \mathbb{P}^1 \setminus \mathcal{E}$,

$$d_1(\Gamma_n)^{-1}(F_{\Gamma_n}^*(\omega_{FS}) - F_{\Gamma_n}^*(\delta_w)) \xrightarrow{\text{weak}^*} 0$$

as $n \to \infty$.

Both results involve the notion of the pullback of a measure by a correspondence. We shall present a very brief discussion — focused on our needs at hand — on how holomorphic correspondences act on currents.

To see that the pullbacks in the above results are measures, we will leave it to the reader to work out — in analogy with the discussion that we present below — that for any volume
form $\omega$, $F^*_T(\omega)$ is a positive measure. Let us now define $F^*_T(\delta_w)$. The formal prescription for the pullback of any current $T$ on $X$ of bidegree $(p, p)$, $p = 0, 1$, is:

$$F^*_T(T) := (\pi_1)_* (\pi_2^*(T) \wedge [\Gamma]).$$

(4.1)

$\Gamma$ determines a current of bidimension $(1, 1)$ via the currents of integration given by its constituent subvarieties $\Gamma_j$. We denote this current by $[\Gamma]$. The above prescription is meaningful only for certain types of currents. In the case of measures: we use the fact that one can define the pullback of a measure by a submersive mapping between manifolds. To begin with, pick a point $w$ from the Zariski-open set $\Omega$ defined in subsection 2.2 (with $X_1 = X_2 = X$, a compact Riemann surface). The prescription (4.1) gives

$$\langle F^*_T(\delta_w), \varphi \rangle \equiv_{\text{by duality}} \langle \pi_2^*(\delta_w) \wedge [\Gamma], \pi_1^* \varphi \rangle := \sum_{j=1}^{N} m_j \langle (\pi_2|_{\Gamma_j})^*(\delta_w), \pi_1^* \varphi \rangle.$$ 

Since, by our description of $\Omega$, $w$ is a regular value of $\pi_2|_{\Gamma_j}$ for each $j = 1, \ldots, N$, the pullback measures above are classically known, and — in our particular case — give:

$$\sum_{j=1}^{N} m_j \langle (\pi_2|_{\Gamma_j})^*(\delta_w), \pi_1^* \varphi \rangle = \sum_{j=1}^{N} m_j \sum_{z \in (\Gamma_j \wedge \pi_j^{-1}(w) \in \Gamma_j} \varphi(z) =: \Lambda[\varphi](w) \quad (\text{provided } w \in \Omega).$$

(4.2)

For any fixed continuous function $\varphi$, $\Lambda[\varphi]$ extends continuously to each $w \in X \setminus \Omega$. We shall still denote this continuous extension of the middle term of (4.2) as $\Lambda[\varphi]$, and use it to define $F^*_T(\delta_w)$: i.e.,

$$\langle F^*_T(\delta_w), \varphi \rangle := \Lambda[\varphi](w) \quad \forall w \in X, \ \forall \varphi \in C(X).$$

(4.3)

Thus, $F^*_T(\delta_w)$ is a measure supported on $F^*_T(w)$. Now, combining Results 4.1 and 4.2 with Proposition 2.1 — taking $\Gamma_1 = \Gamma_2 = \Gamma_3 = \cdots = \Gamma$ in Result 4.1 and $\Gamma_n = \Gamma^{\sim n}$, $n = 1, 2, 3, \ldots$, in Result 4.2 — we get the following:

**Fact 4.3.** Let $\Gamma$ be a holomorphic correspondence on $\mathbb{P}^1$ such that $d_0(\Gamma) < d_1(\Gamma)$. There exist a polar set $E \subset \subset \mathbb{P}^1$ and a regular Borel probability measure $\mu_{\Gamma}$ such that for each $w \in \mathbb{P}^1 \setminus E$

$$d_1(\Gamma)^{-n} F^*_\Gamma^{\sim n}(\delta_w) \xrightarrow{\text{weak*}} \mu_{\Gamma}$$

as measures, as $n \to \infty$.

The measure $\mu_{\Gamma}$ places no mass on polar sets.

We must state that we do not claim the above fact as an original result. It is already well known to those who have studied [5]; but a precise statement in the above form is hard to find in [5].

The following lemma will be useful in the proof of Theorem 1.4

**Lemma 4.4.** Let $\Gamma$ be any holomorphic correspondence with the properties stated in Fact 4.3 above, and let $\mu_{\Gamma}$ be the measure associated to $\Gamma$. Let $C = \{w_0, w_1, w_2, \ldots\}$ be a countable subset of $\mathbb{P}^1$. Given any $M \in \mathbb{N}$ and $\varepsilon > 0$, we can find a simply-connected domain $U \equiv U(\varepsilon, M)$ that is biholomorphic to $\mathbb{D}$ such that:

- $U \cap \{w_\nu : 0 \leq \nu \leq M\} = \emptyset$, and
- $\mu_{\Gamma}(U) > 1 - \varepsilon$.

**Proof.** Since $\mu_{\Gamma}$ does not place any mass on polar sets (and is a finite measure), we can find a simply-connected neighbourhood $D_{\varepsilon}$ of $w_0$ with $\overline{D_{\varepsilon}} \cap \{w_\nu : 1 \leq \nu \leq M\} = \emptyset$ such that

$$\mu_{\Gamma}(\mathbb{P}^1 \setminus \overline{D_{\varepsilon}}) = 1 - \varepsilon/2.$$
If \( M = 0 \), then \( U := (\mathbb{P}^1 \setminus \overline{D}_\varepsilon) \) has the desired properties, and we are done.

For the remainder of this proof, we will assume that \( M \geq 1 \). If we set

\[
V := \mathbb{P}^1 \setminus \left( \overline{D}_\varepsilon \cup \{ w_\nu : 1 \leq \nu \leq M \} \right),
\]

then by (4.4), \( \mu_T(V) = 1 - \varepsilon / 2 \). Without loss of generality, we may assume that \( w_0 \) is the point at infinity, whence \( (\text{supp}(\mu_T) \setminus \overline{D}_\varepsilon) \subset \mathbb{C} \). Let \( m \) denote the two-dimensional Lebesgue measure on \( \mathbb{C} \) and let

\[
\mu_T = \mu_s + \mu_{\text{Leb}}
\]
denote the Lebesgue decomposition of \( \mu_T \) such that \( \mu_s \perp m \) and \( \mu_{\text{Leb}} \ll m \). Let \( Q_z(r) \) denote the closed square in \( \mathbb{C} \) with edges parallel to the real and imaginary axes of \( \mathbb{C} \), centre \( z \) and edge-length \( r \). Then, we know that (see [20, Theorem 10.48], for instance)

\[
\lim_{r \to 0^+} \frac{\mu_s(Q_z(r))}{m(Q_z(r))} = 0 \quad \text{for } m\text{-a.e. } z.
\]

(4.5)

Let \( G \) denote the set on which the equality in (4.5) holds and let \( B := \mathbb{C} \setminus G \).

Note that \( \{ w_\nu : 1 \leq \nu \leq M \} \) need not be disjoint from \( B \). Since \( \mu_T \) places no mass on polar sets, \( \mu_s(\{ w_\nu \}) = 0 \) for \( 1 \leq \nu \leq M \). Thus, we can find mutually disjoint closed squares \( S_1, \ldots, S_M \), with \( S_\nu \) centred at \( w_\nu \), that are so small that \( \mu_s(S_\nu) < \varepsilon / 4M, 1 \leq \nu \leq M \). Now note that \( B \) has empty interior. Thus, we can find a piecewise smooth path \( \sigma : [0, 1] \to \mathbb{C} \) such that, writing \( A := \sigma([0, 1]) \),

- \( \sigma(\nu/M) = w_\nu, 1 \leq \nu \leq M \);
- \( V \setminus A \) is simply connected; and
- \( A \setminus \{ \cup_{1 \leq \nu \leq M} S_\nu \} = \cup_{1 \leq \nu \leq M} A_\nu \), where each \( A_\nu \) is a sub-arc of \( A \) lying in \( G \).

Let us set \( U := (V \setminus A) \). Now, by (4.4) and the fact that \( \mu_{\text{Leb}} \ll m \) it follows that

\[
\mu_{\text{Leb}}(U) \geq \mu_{\text{Leb}}(V) - \mu_{\text{Leb}}(A) = \mu_{\text{Leb}}(V) - \int_A 1 \, d\mu_{\text{Leb}} = \mu_{\text{Leb}}(V).
\]

(4.6)

In view of (4.5) and the fact that \( A_\nu \subset G, 1 \leq \nu \leq M \), we can find a covering of each \( A_\nu \) by small closed squares each of whose \( \nu \)-measure is \( O(\delta^2) \) and such that the number of such squares is \( O(1/\delta) \) as \( \delta \to 0^+ \). By this—and by the fact that \( \mu_s(S_\nu) < \varepsilon / 4M, 1 \leq \nu \leq M \)—we can show that \( \mu_s(A) < \varepsilon / 2 \). Then, in view of (4.6), \( U \) has the required properties.

\[\Box\]

4.2. The distribution of repelling periodic points. The proof of Theorem 1.4 follows from an auxiliary theorem stated in the language of correspondences: i.e., Theorem 4.5 below. This theorem is in the same spirit as Théorème 4.1 of [4] by Dinh. The proofs of both theorems rely on an idea of Briend–Duvau in [2]. Dinh’s result, unlike ours, has an extremely technical hypothesis, but [4, Théorème 4.1] is about sequences of general holomorphic correspondences on a compact Riemann surface. The form of the correspondence appearing in Theorem 4.5 is such that many of the obstacles in the proof of [4, Théorème 4.1] can be circumvented (the setting of \( \mathbb{P}^1 \) of Theorem 4.5 is unimportant to its proof, but it is well known that correspondences of the type featured below on a compact hyperbolic Riemann surface are dynamically uninteresting).

For a correspondence of the form (3.3) on \( \mathbb{P}^1 \), we say that a point \( x \in \mathbb{P}^1 \) is a repelling fixed point if \( (x, x) \in \Gamma \cap \{(z, w) \in \mathbb{P}^1 \times \mathbb{P}^1 : z = w\} \) and is a repelling fixed point for some \( g_j \). For greater clarity, we will sometimes refer to this \( x \) as a repelling fixed point associated to \( g_j \). If \( x \) is a repelling fixed point, then note that its multiplicity is

\[
\text{Card}\{1 \leq j \leq N : x \text{ is associated to } g_j\}.
\]
(Recall that the local intersection multiplicity of \( \{(z, w) \in \mathbb{P}^1 \times \mathbb{P}^1 : z = w \} \) with graph(g\(_j\)) at \((x, x)\), if \(x\) is repelling fixed point of \(g_j\), is 1.)

**Theorem 4.5.** Let \( \Gamma \) be a correspondence of the form

\[
\Gamma = \sum_{1 \leq j \leq N} \text{graph}(g_j)
\]

on \( \mathbb{P}^1 \), where each \( g_j \) is a rational map, with \( g_1, \ldots, g_N \) not necessarily distinct, and \( \deg(g_j) \geq 2 \) for at least one \( j, 1 \leq j \leq N \). Write

\[\mathcal{R}(n)^* := \text{the list of repelling fixed points of } \Gamma^n \text{ repeated according to multiplicity}.\]

Then, for the sequence of measures \( \{\mu_n\} \), \( \mu_n \) as defined below, we have:

\[
\mu_n := d_1(\Gamma)^{-n} \sum_{x \in \mathcal{R}(n)^*} \delta_x \text{ weak}^* \xrightarrow{\mu_\Gamma} \text{ as } n \to \infty,
\]

where \( \mu_\Gamma \) is as given by Fact 4.3.

**Proof.** Before we proceed, we must clarify that we shall follow the notation discussed prior to Lemma 3.3 when working with lists. Also, let us abbreviate:

\[D := d_1(\Gamma).\]

By Bézout’s Theorem for \( \mathbb{P}^1 \times \mathbb{P}^1 \), see [12, Chapter IV, Section 2], we have

\[
\# \mathcal{R}(n)^* \leq Dn + \#(\text{list of irreducible branches of } \Gamma^n) = Dn + N_n,
\]

whence \( 0 \leq \text{mass}(\mu_n) < 2 \). From this, and the fact that \( \mathbb{P}^1 \) is compact, there exists a subsequence \( \{\mu_{n_k}\} \) and a Borel measure \( \bar{\mu} \) such that

\[
\mu_{n_k} \xrightarrow{\text{weak}^*} \bar{\mu} \text{ as } k \to \infty. \tag{4.9}
\]

We shall show that for any such \( \{\mu_{n_k}\} \), the associated limit measure \( \bar{\mu} \) equals \( \mu_\Gamma \). To show this, it suffices to meet the following goal: to show that for any \( \varphi \in C(\mathbb{P}^1; \mathbb{R}) \) such that \( \|\varphi\|_\infty = 1 \), and for any \( \varepsilon > 0 \),

\[
\left| \int_{\mathbb{P}^1} \varphi d\bar{\mu} - \int_{\mathbb{P}^1} \varphi d\mu_\Gamma \right| < \varepsilon,
\]

for each limit measure \( \bar{\mu} \) described by (4.9).

Toward this goal, we may without confusion — and for simplicity of notation — relabel any subsequence featured in (4.9) as \( \{\mu_{n_k}\} \). Fix an \( \varepsilon > 0 \). Let \( L \in \mathbb{Z}_+ \) be so large that

\[
\left( \frac{N}{D} \right)^L (N + 1) \tau < \frac{\varepsilon}{16}, \tag{4.10}
\]

where \( \tau \) is as in Lemma 3.5. Taking

\[C = \bigcup_{n=1}^{\infty} \text{crit}(\Gamma^n)\]

in Lemma 4.4 (it will not matter if \( C \) is finite), and enumerating \( C \) so that \( C_L = \{w_m \in C : 0 \leq m \leq M\} \) for some \( M \in \mathbb{N} \) (where \( C_L \) is as introduced in Section 3), we can find three simply-connected domains \( W' \Subset W \Subset U \), each biholomorphic to \( \mathbb{D} \), such that

\[\mu_\Gamma(W'), \mu_\Gamma(W), \mu_\Gamma(U) > 1 - \varepsilon/8 \text{ and } U \cap C_L = \emptyset.\]

By (4.10) and Lemma 3.5 it follows that \( \Gamma^n \) admits at least \( (1 - \varepsilon/16)D^n \) regular inverse branches that are holomorphic on \( U \), counting according to multiplicity. Then, by Lemma 3.3, there exists a positive integer \( N_1 \equiv N_1(\varepsilon) \geq L \) such that, for \( n \geq N_1 \), at least
$D^n(1 - \varepsilon/8)$ (counting according to multiplicity) of the aforementioned regular inverse branches—denote these branches by $^n\gamma$—satisfy
\[
\operatorname{diam}(\gamma(W)) \leq B_\varepsilon \sqrt{N^n/D^n} \quad \text{(for } n \geq N_1),
\] (4.11)
where $B_\varepsilon > 0$ is a constant that depends only on $\varepsilon$. Let $\mathcal{F}(n)^*$ be the list of branches having the above property. So, $\sharp \mathcal{F}(n)^* \geq (1 - \varepsilon/8)D^n$ (for $n \geq N_1$).

At this stage, we have obtained objects—and a few estimates about them—that will allow us to complete our proof as in the last two paragraphs of the proof of [4, Théorème 4.1]. However, since one key point in the latter arises from a hypothesis in [4] that we do not make, we should provide a few more details. Since $\mu_\Gamma$ does not place mass on polar sets, we can find a point $w_0 \in W'$ such that for the measures $\mu_n^{w_0}$, $\mu_{n0}$ as defined below, we have according to Fact 4.3:
\[
\mu_n^{w_0} := D^{-n} F_{\Gamma^n}(\delta_{w_0}) \overset{\text{weak}^*}{\to} \mu_\Gamma.
\] (4.12)

Consider the list $\mathcal{F}(n)^* := \{^n\gamma \text{ in } \mathcal{F}(n)^* : ^n\gamma(w_0) \in W'\}$. By our construction of $W'$ and by the size of the list $\mathcal{F}(n)^*$, we have:
\[
1 - \varepsilon/8 \leq \mu_\Gamma(W') \leftarrow \mu_n^{w_0}(W') \leq \frac{\# \mathcal{F}(n)^*}{D^n} + \frac{\varepsilon}{8}.
\]

Using this and (4.12), we can find an integer $N_2 \equiv N_2(\varepsilon)$, $N_2 \geq N_1$, such that
\[
\# \mathcal{F}(n)^* \geq (1 - \varepsilon/2)D^n \quad \forall n \geq N_2.
\] (4.13)

Consider, to begin with, $n \geq N_1$. For each $^n\gamma$ listed in $\mathcal{F}(n)^*$, $^n\gamma(W) \cap W' \neq \emptyset$. As $W' \subseteq W$, it follows from (4.11) that there is a positive integer $N_3 \equiv N_3(\varepsilon)$ such that
\[
^n\gamma(W) \subseteq W \quad \forall^n\gamma \text{ in } \mathcal{F}(n)^* \quad \text{and} \quad \forall n \geq N_3.
\]

Since $W$ is biholomorphic to the unit disc, it follows from the Wolff–Denjoy theorem that, associated to each $^n\gamma$ referenced above, there is a unique attracting fixed point of $^n\gamma|_W$; call it $z(^n\gamma)$. Observe that, since $^n\gamma$ is a regular inverse branch, $z(^n\gamma)$ is a repelling fixed point of $\Gamma^n$. Let us write
\[
\tilde{\nu}_n := D^{-n} \sum_{^n\gamma \in \mathcal{F}(n)^*} \delta_{z(^n\gamma)}.
\]

Arguing as above, there exists a subsequence $\{\tilde{\nu}_{n_k}\}$ and a Borel measure $\tilde{\nu}$ such that
\[
\tilde{\nu}_{n_k} \overset{\text{weak}^*}{\to} \tilde{\nu} \quad \text{as } k \to \infty.
\] (4.14)

Fix a function $\varphi \in C(\mathbb{P}^1; \mathbb{R})$ such that $\|\varphi\|_\infty = 1$. Then, owing to the fact that each $z^{(n)}$ is a repelling fixed point of $\Gamma^n$, the count (4.8), and the estimate (4.13), we have
\[
\left| \int_{\mathbb{P}^1} \varphi \, d\tilde{\nu}_{n_k} - \int_{\mathbb{P}^1} \varphi \, d\mu_{n_k} \right| \leq \frac{N^n}{D^n} + \frac{\varepsilon}{2} \quad \forall k : n_k \geq \max(N_2, N_3).
\]

Observe that the above estimate holds true irrespective of the subsequence $\{\tilde{\nu}_{n_k}\}$ and of $\varepsilon > 0$. Thus, keeping in mind the goal stated at the beginning of the proof and the fact that $\varepsilon > 0$ is arbitrary, it suffices to meet the following revised goal: to show that for any $\varphi \in C(\mathbb{P}^1; \mathbb{R})$ with $\|\varphi\|_\infty = 1$, and for any $\varepsilon > 0$,
\[
\left| \int_{\mathbb{P}^1} \varphi \, d\nu - \int_{\mathbb{P}^1} \varphi \, d\mu_\Gamma \right| < 2\varepsilon,
\]
for each limit measure described by (4.14).
Observe that there is no loss of generality in relabelling a subsequence \( \{ \tilde{\nu}_n \} \) as \( \{ \tilde{\nu}_n \} \) for the purposes of the revised goal. To achieve this, we introduce the auxiliary measures

\[
\mu'_n := D^{-n} \sum_{n \gamma \in \tilde{\mathcal{F}}(n)} \delta_{n \gamma(w_0)}.
\]

In view of (4.12), (4.13) and (4.14), we can find an integer \( N_* = N_*(\varepsilon, \varphi) \) sufficiently large that—for a fixed \( \varphi \) as described above—we have:

\[
\left| \int_{\mathbb{P}^1} \varphi \, d{m_n} - \int_{\mathbb{P}^1} \varphi \, d{m'_n} \right| \leq \varepsilon/2 \quad \forall n \geq N_*,
\]

where the pair of measures \( (m_n, m'_n) \) is either \( (\mu, \mu^{w_0}) \) or \( (\mu^{w_0}, \mu') \) or \( (\tilde{\nu}_n, \tilde{\nu}) \). We now need to account for the pair of measures \( (\mu'_n, \tilde{\nu}_n) \). Since \( z^{(n \gamma)} \), \( n \gamma(w_0) \in n \gamma(W) \) for each \( n \gamma \) in \( \tilde{\mathcal{F}}(n)^* \) \( n \) sufficiently large, by raising the value of \( N_* \) further if necessary we can ensure, by continuity of \( \varphi \) and by (4.11), that

\[
|\varphi(z^{(n \gamma)})) - \varphi(z^{(n \gamma)}))| < \varepsilon/2 \quad \forall n \gamma \in \tilde{\mathcal{F}}(N_*)^*.
\]

Our revised goal is achieved through the last two inequalities by using a standard triangle-inequality argument. \( \square \)

The proof of Theorem 1.4. Given a finitely generated rational semigroup \( S \), having fixed a set of generators \( \mathcal{G} = \{ g_1, \ldots, g_N \} \), we apply Theorem 4.5 to the correspondence \( \Gamma_{\mathcal{G}} \), which is given by (1.2).

By (a generalisation of) the composition formula (2.5), it is easy to see that

\[
\tilde{\mathcal{F}}(n)^* = R(n; \mathcal{G})^* \quad \text{for} \quad \Gamma = \Gamma_{\mathcal{G}}.
\]

The measures \( \mu_n \) in (1.5) are special cases of the measures \( \mu_n \) considered in Theorem 4.5. Hence, from (4.7), Theorem 1.4 follows. \( \square \)

Remark 4.6. The conclusion of Theorem 1.4 for the case of the semigroups \( \{ f^n : n \in \mathbb{N} \} \), where \( f \) is a rational map with \( \deg(f) \geq 2 \), follows easily from [11, §3, Theorem 3]. A possible approach to proving Theorem 1.4 is suggested by the proof of [11, §3, Theorem 3] (from which we borrow one key idea). But the expanding features of the aforementioned \( f \) play such a significant role in the latter proof that the conclusion of Theorem 1.4 that is obtainable by a more “direct” approach holds only for semigroups \( \langle g_1, \ldots, g_N \rangle \) such that \( \deg(g_j) \geq 2 \) for each \( j = 1, \ldots, N \). It may be possible, with much more effort, to improve upon the latter without appealing to any auxiliary object, but the use of the correspondence \( \Gamma_{\mathcal{G}} \) has certain advantages. For instance, it reveals that the condition (1.4) endows \( \Gamma_{\mathcal{G}} \) with expanding features that are adequate to be useful in applications. Here, we understand “expanding” to mean the existence of sufficiently many holomorphic inverse branches of \( \Gamma_{\mathcal{G}}^n \), \( n = 1, 2, 3, \ldots \), the diameters of whose ranges shrink to zero as \( n \to \infty \). This is the content of Lemma 3.3, which is actually a phenomenon about general holomorphic correspondences. Of course, Lemma 3.5 plays a facilitating role for the use of Lemma 3.3, but Lemma 3.5 can also be stated for a more general class of correspondences.

5. The proof of Theorem 1.6

The proof of Theorem 1.6 requires the following result.

Lemma 5.1. Let \( \mu \) be a probability measure on a set \( X \subset \mathbb{C} \). If there exist positive constants \( c, t \) and \( r_0 \) such that, for each \( r \in (0, r_0) \),

\[
\mu(D(z; r)) \leq cr^t
\]
for every disc $D(z;r)$ with centre $z$ and radius $r$ that has non-empty intersection with $X$, then $\dim_H(X) \geq t$.

The above lemma is an immediate consequence of a standard result, see [6, Mass distribution principle, §4.1], for instance. Our proof also requires Theorem 4.5: specifically, that it implies that for the measure $\mu_f$ discussed therein, $\text{supp}(\mu_f) \subseteq J((g_1, \ldots, g_N))$.

Theorem 1.6 extends a result of Garber [7], on the Julia set of a single rational map of degree $\geq 2$, to finitely generated semigroups.

The proof of Theorem 1.6. The strategy of our proof is to consider a sequence of correspondences related to the semigroup $S$ whose equilibrium measures are subsets of $\mathcal{J}(S)$. We shall see that a lower bound for the Hausdorff dimension of the supports of the equilibrium measures of each of these correspondences will give a progressively better lower bound for $\dim_H(\mathcal{J}(S))$.

As in the statement of the theorem, we consider a set of generators

$$\mathcal{G} = \{g_1, \ldots, g_N\},$$

and enumerate $\mathcal{G}$ so that $\text{deg}(g_N) = \max_{1 \leq j \leq N} \text{deg}(g_j)$. We define the correspondences

$$\Gamma(k) := \sum_{1 \leq j \leq (N-1)} \text{graph}(g_j) + k \cdot \text{graph}(g_N), \quad k = 1, 2, 3, \ldots$$

Let us denote the equilibrium measure $\mu_{\Gamma(k)}$ as simply $\mu(k)$. For a fixed $k$, let $\{\mu_n(k)\}$ be the sequence of measures approximating $\mu(k)$ in the sense of (4.7). Then:

$$\text{supp}(\mu_n(k)) = \{z : z \text{ is a repelling fixed point of some word } w \text{ such that } |w|_{\mathcal{G}} = n\}.$$

Furthermore, given $m, n \in \mathbb{Z}_+$, it is easy to see that

$$\text{supp}(\mu_m(k)), \text{supp}(\mu_n(k)) \subseteq \text{supp}(\mu_{mn}(k)).$$

Thus, by Theorem 4.5, we conclude that

$$\text{supp}(\mu(k)) \subseteq \{z : z \text{ is a repelling fixed point of some } g \in S\}, \quad \forall k.$$

By Result 1.3 we get:

$$\text{supp}(\mu(k)) \subseteq \mathcal{J}(S) \quad \forall k. \quad (5.1)$$

**Step 1. A lower bound for $\dim_H(\text{supp}(\mu(k)))$.**

Fix a $k \in \mathbb{Z}_+$. We rewrite $\Gamma(k)$ in the form given by (3.3), wherein the index $j$ runs from 1 to $(N + k - 1)$ and

$$g_j = \begin{cases} g_j, & \text{if } 1 \leq j \leq (N - 1), \\ g_N, & \text{if } N \leq j \leq (N + k - 1). \end{cases}$$

There is no loss of generality in assuming that $\mathcal{J}(S) \subset \mathbb{C}$ and that $g_j$ has no poles on $S$, $1 \leq j \leq N$. Then, our hypothesis on the maps $G_j$—as defined in the statement of Theorem 1.6—translates to (for simplicity of notation, we shall work with $g_j$ below rather than with the purely auxiliary $G_j$):

$$|g_j'(\xi)| \leq M \quad \forall \xi \in \mathcal{J}(S) \text{ and for } j = 1, \ldots, (N + k - 1),$$

where, by the compactness of $\mathcal{J}(S)$, $M$ is finite. In what follows, we shall abbreviate $\mathcal{J}(S)$ to $\mathcal{J}$. Set

$$\lambda(k) = \frac{\log(d_1(\Gamma(k))/d_0(\Gamma(k)))}{\log(M)} = \frac{\log((D + (k-1) \text{deg}(g_N))/(N + k - 1))}{\log(M)},$$
where $D$ has the same meaning as in Section 4. Fix $t \in (0, \lambda(k))$, and abbreviate

$$R(k) := \frac{D + (k-1) \deg(g_N)}{N + k - 1} \equiv \frac{d_1(k)}{d_0(k)}.$$ 

For a positive number $\varepsilon$, let us write

$$\mathcal{J}^\varepsilon := \cup_{\xi \in \mathcal{I}(S)} D(\xi; \varepsilon), \quad \text{and} \quad \mathcal{J} := \overline{\mathcal{J}(S)}^\varepsilon.$$

By Result 1.3, $1 < M < R(k)^{1/t}$. Owing to this, and to our assumption that $g_j$ has no critical points on $\mathcal{J}$, $j = 1, \ldots, N$, we can find:

- $\delta_1 > 0$ such that $g_j'(\xi) \neq 0$ for every $\xi \in J^{2\delta_1}, j = 1, \ldots, (N + k - 1)$;
- $r(\xi) > 0$ such that $g_j|_{D(\xi; r(\xi))}$ is injective, $j = 1, \ldots, (N + k - 1)$, as $\xi$ varies through $J^{2\delta_1}$;
- $\varepsilon_t > 0$ such that $|g_j'(\xi)| < R(k)^{1/t}$ for every $\xi \in J^{\varepsilon_t}, j = 1, \ldots, (N + k - 1)$.

Let

$$\delta_2 := \text{the Lebesgue number of the open cover } \{D(\xi; r(\xi)) : \xi \in J^{2\delta_1}\}.$$

Write $r_t := \min(\delta_1, \delta_2, \varepsilon_t)/4$. We will need to work with the partition $\cup_{n=1}^\infty I(l, k)$ of $(0, r_t]$,

$$I(l, k) := (r_t R(k)^{1-t}, r_t R(k)^{(1-l)/t}], \quad l = 1, 2, 3, \ldots$$

Since $\mu(k)$ places no mass on polar sets, by Fact 4.3, we can find a point $w \in \text{supp}(\mu(k))$—i.e., by (5.1), $w \in J$—such that for the measures $\mu_n(w, k)$ as defined below, we have:

$$\mu_n(w, k) := d_1(\Gamma(k))^{-n} F_{\Gamma(k\circ n)}^*(\delta_w) \underset{\text{weak}}{\rightarrow} \mu(k).$$

It is easy to see from the definition of $J$—see [8, Theorem 2.1]—that $f^{-1}\{w\} \subset J$ for each $f \in S$. Hence, $\text{supp}(\mu_n(w, k)) = (F_{\Gamma_n\circ n}^*)^1(w) \subset J$. Let us fix $r \in (0, r_t]$ and consider a disc $D(z; r)$ such that $D(z; r) \cap J \neq \emptyset$. Let $l \in \mathbb{Z}_+$ be such that $r \in I(l, k)$. Then, from the descriptions of the parameters above:

a) $D(z; r) \not\subset D(x(z); 2r_t R(k)^{(1-l)/t}) \subset D(x(z); \varepsilon_t/2) \cap D(x(z); \delta_1/2)$ for some point $x(z)$ belonging to $J$.

b) $|g_j'(\xi)| < R(k)^{1/t}$ for every $\xi \in D(z; r), j = 1, \ldots, (N + k - 1)$.

c) $g_j$ is injective on $D(z; r)$ for $j = 1, \ldots, (N + k - 1)$.

With these three assertions, we can prove the following claim, which is the central assertion of this proof. Once again, we remind the reader that the counts made in the claim below are according to multiplicity, and we shall distinguish between sets and lists using the notation introduced in Section 3. Also, in the style of Section 1, let us write $(F^n)^\dagger := (F_{\Gamma_n\circ n})^\dagger$.

Claim. Let $r \in (0, r_t]$ and let $D(z; r)$ be an open disc such that $D(z; r) \cap J \neq \emptyset$. Let $l \in \mathbb{Z}_+$ such that $r \in I(l, k)$. Then, for any $n \in \mathbb{N},$

$$\sharp((F^n)^\dagger(w) \cap D(z; r))^\dagger \leq \max\left(d_0(k)^n, d_1(k)^{n-l+1} d_0(k)^{\text{min}(n,l)-1}\right).$$

We will prove this claim by induction on the parameter $n$. Note that the claim is trivial when $n = 0$. Let us assume that the claim is true for $n = m$ for some $m \in \mathbb{N}$. We will study what this implies for $n = m + 1$. We have two cases to analyse.

Case 1. $r \in I(1, k)$

In this case, the claim is obvious for $n = m + 1$ by the meaning of $d_1(\Gamma(k)) =: d_1(k)$. 

Case 2. $r \in I(l, k)$ and $l \geq 2$.

Let $p$ denote any point in the set $(F^{m+1})^{\dagger}(w) \cap D(z; r)$ (which might occur with multiplicity greater than 1). We need to define a few sets:

$$S(m+1) := \{1 \leq j \leq (N + k - 1) : (F^{m+1})^{\dagger}(w) \cap D(z; r) \cap g_j^{-1}((F^{m})^{\dagger}(w)) \neq \emptyset\};$$

$$S(p, m+1) := \{j \in S(m+1) : p \in g_j^{-1}((F^{m})^{\dagger}(w))\};$$

and the list

$$L(j, p, m)^* := \text{the list of all points } \zeta \in (F^{m})^{\dagger}(w), \text{ repeated}
\text{ according to multiplicity, such that } p \in g_j^{-1}\{\zeta\}. \quad (5.2)$$

A point $p \in (F^{m+1})^{\dagger}(w)$ may have to be counted with multiplicity $\geq 2$ precisely because it could occur as the pre-image under $g_j$ of some point $\zeta(j) \in (F^{m})^{\dagger}(w)$ for more than one $j$, and each $\zeta(j)$ itself must be counted in its turn according to its multiplicity. Therefore:

$$\sharp((F^{m+1})^{\dagger}(w) \cap D(z; r))^* = \sum_{p \in (F^{m+1})^{\dagger}(w) \cap D(z; r)} \sum_{j \in S(p, m+1)} \sharp L(j, p, m)^*. \quad (5.3)$$

Note that the indices of the two sums above run through sets, whereas $L(j, p, m)^*$ is a list. By (c) above, we have that for each relevant $p$ in the above equation and each $j \in S(p, m+1)$ associated to it, $g_j$ is injective on $D(z; r)$. Using this, and interchanging the order of summation in the above equation:

$$\sharp((F^{m+1})^{\dagger}(w) \cap D(z; r))^* = \sum_{j \in S(m+1)} \sharp((F^{m})^{\dagger}(w) \cap g_j(D(z; r)))^*. \quad (5.3)$$

Now, owing to (b) above, it follows from an elementary computation that $g_j(D(z; r)) \subset D(g_j(z); rR(k)^{1/t})$. Furthermore, by the definition of $S(m+1)$ and as $(F^{n})^{\dagger}(w) \subset J$ for each $n \in \mathbb{N}$,

$$j \in S(m+1) \Rightarrow g_j(D(z; r)) \cap J \text{ contains some point of } (F^{m})^{\dagger}(w).$$

From the last two facts, we have:

$$j \in S(m+1) \Rightarrow D(g_j(z); rR(k)^{1/t}) \cap J \neq \emptyset. \quad (5.4)$$

By (5.3), we have

$$\sharp((F^{m+1})^{\dagger}(w) \cap D(z; r))^* \leq \sum_{j \in S(m+1)} \sharp((F^{m})^{\dagger}(w) \cap D(g_j(z); rR(k)^{1/t}))^*. \quad (5.3)$$

By (5.4), each of the discs $D(g_j(z); rR(k)^{1/t})$ featuring in the right-hand side of the above equation satisfies the hypothesis of our claim above. Then, from the last inequality, our inductive assumption, and from the fact that $rR(k)^{1/t} \in I(l-1, k)$, we have

$$\sharp((F^{m+1})^{\dagger}(w) \cap D(z; r))^* \leq d_0(k) \max(d_0(k)^m, d_1(k)^{m-(l-1)} + d_0(k)^{(\min(m, (l-1))-1)})$$

$$= \max(d_0(k)^{(m+1)}, d_1(k)^{(m+1)} - l + 1 d_0(k)^{(\min(m+1), l)-1}).$$

From Cases 1 and 2, our claim is true for $n = m + 1$. By induction, our claim it follows for all $n \in \mathbb{N}$. \hfill \blacktriangleleft

Fix a disc $D(z; r)$, $r \in (0, r_l]$, such that $D(z; r) \cap J \neq \emptyset$. From the above claim, we get that for sufficiently large $n$

$$d_1(k)^{-n} F_{\Gamma(k)}^{\bullet}(\delta_w)(D(z; r)) \leq \left(\frac{d_1(k)}{d_0(k)}\right)^{1-l} \leq \frac{R(k)}{(r_l)^{1/t}},$$

but
where \( l \) is the unique integer such that \( r \in I(l, k) \). By the limiting behaviour of the above measures, we see from above that we have a constant \( c \equiv c(k, t) \) such that
\[
\mu(k)(D(z; r)) \leq cr^t \quad \text{(provided \( r \in (0, r_t], r_t \) as fixed above)}.
\]

By Lemma 5.1, and the fact that \( t \) was picked arbitrarily from \( (0, \lambda(k)) \), we get
\[
\dim_H(J) \geq \dim_H(\text{supp}(\mu(k))) \geq \frac{\log(D + (k-1)\deg(g_N))}{\log(M)} \geq \frac{\log((D + (k-1)\deg(g_N))/(N+k-1))}{\log(M)}.
\] (5.5)

**Step 2.** A lower bound for \( \dim_H(J) \).

Observe
\[
\frac{D + (k - 1)\deg(g_N)}{N + k - 1} = \frac{D/\deg(g_N)}{(N-k+1)} + 1 \rightarrow \deg(g_N) \quad \text{as} \; k \rightarrow +\infty.
\]

From this, (5.1) and (5.5), the lower bound (1.6) for \( \dim_H(J) \) follows.

**Step 3.** The sharpness of the inequality (1.6)

It is well known that (1.6) is sharp for the semigroups \( \{f^n : n \in \mathbb{N}\} \), where \( f \) is a rational map. The point that we wish to make is that (1.6) is sharp for rational semigroups having \( N \) generators, for any given \( N \). To this end, fix \( N \in \mathbb{Z}_+ \). Now let \( 1 < d_1 < d_2 < \cdots < d_N \) be positive integers such that
\[
z^{d_j} \notin \langle z^{d_1}, \ldots, z^{d_j-1} \rangle, \quad j = 2, \ldots, N.
\]

Let \( S_N := \langle z^{d_1}, \ldots, z^{d_N} \rangle \). For any rational semigroup \( S \) having at least one element of degree at least 2
\[
J(S) = \bigcup_{g \in S} J(g);
\]
see [10, Corollary 2.1]. Thus, \( J(S_N) = \partial \mathbb{D} \). By definition,
\[
M = \sup \{ d_j \vert \xi^{d_j-1} \mid \xi \in \partial \mathbb{D}, \; j = 1, \ldots, N \} = d_N.
\]

It is also obvious that none of the maps \( z \mapsto z^{d_j}, j = 1, \ldots, N \), has critical points on \( \partial \mathbb{D} \). It is trivial to see now that the inequality (1.6) holds true for \( S_N \) as an equality. \( \square \)
