Markets with Production and constant number of goods

Jugal Garg and Ravi Kannan [Nikhil Devanur]

First, assume no production.

First, assume no production.

◆□ ▶ < 圖 ▶ < 圖 ▶ < 圖 ▶ < 圖 • 의 Q @</p>

▶ *n* agents. *m* goods.

- First, assume no production.
- ▶ *n* agents. *m* goods.
- Agent *i* has a utility function $U_i(x_i)$, where

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

- First, assume no production.
- ▶ *n* agents. *m* goods.
- Agent *i* has a utility function $U_i(x_i)$, where
 - x_i is his "consumption bundle" (amount of each good consumed) given as a *m* vector of non-negative reals. (eg. (number of loaves of bread, liters of milk)).
 U_i is concave (Diminishing returns) and here assume piece-wise linear (we call it PLC) utilities.

- *i* always agent. *j* always good.
- 2 models : (i) Each agent comes with a fixed amount of money or (ii) a fixed bundle of goods.

Price : a *m* vector giving unit price for each good. [Cost Linear]

 Price : a *m* vector giving unit price for each good. [Cost Linear]

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

Equilibrium Price : A price at which

- Price : a *m* vector giving unit price for each good. [Cost Linear]
- Equilibrium Price : A price at which
 - if P_i is the set of bundles achieving maximum utility for agent i subject to budget (each agent maximizes separately ignoring others),

- Price : a *m* vector giving unit price for each good. [Cost Linear]
- Equilibrium Price : A price at which
 - if P_i is the set of bundles achieving maximum utility for agent i subject to budget (each agent maximizes separately ignoring others),
 - ► there exists a set of bundles x₁ ∈ P₁, x₂ ∈ P₂,... so that the market clears exacly.

- Price : a *m* vector giving unit price for each good. [Cost Linear]
- Equilibrium Price : A price at which
 - if P_i is the set of bundles achieving maximum utility for agent i subject to budget (each agent maximizes separately ignoring others),
 - ► there exists a set of bundles x₁ ∈ P₁, x₂ ∈ P₂,... so that the market clears exacly.

Nash : An equilibrium price always exists.

- Price : a *m* vector giving unit price for each good. [Cost Linear]

- Nash : An equilibrium price always exists.
- Central Problem in Computational Economics : Algorithm to find an equilibrium price.
- Our interest : Can we do it in poly time ? Yes, for constant number of goods.
- Note : If prices are given, each agent's problem is an LP maximize min of several linear function. If prices are unknowns, problem is non-linear – (price)(amount of good bought).

 Deng Devanur Papdimitriou, Saberi Vazirani; Jain gave a poly-time algorithm for linear utilities.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

- Deng Devanur Papdimitriou, Saberi Vazirani; Jain gave a poly-time algorithm for linear utilities.
- In many cases equilibrium prices and/or allocations are irrational numbers and hence one has to settle for approximations to the equilibrium. For instance, Codenotti et al. [CPV05] give an algorithm based on the ellipsoid method to compute an approximate equilibrium in markets with utilities that satisfy the so called weak gross substitutes (WGS) property. [Note : Approximate equilibrium very different beast than exact one.]

- Deng Devanur Papdimitriou, Saberi Vazirani; Jain gave a poly-time algorithm for linear utilities.

[Note : Approximate equilibrium very different beast than exact one.]
- For non-constant number of goods, with PLC concave utilities, (or even Leontief utilities) PPAD hard. Codenotti, Saberi, Varadarajan and Ye
 - Leontief utilities (special case of PLC)

$$U_i(x_i) = \min_j x_{ij} / \phi_{ij}.$$

Our Results

Devanur, K. Polynomial time algorithm for finding an exact equilibrium when the number of goods in constant. We also do the same for the case when the number of agents is constant provided the utilities are separable –

$$U_i(x_i) = \sum_j U_{ij} x_{ij}.$$

An important open question : Poly time alg for the case when number of agents is constant, but utilities are not separable.

- Jugal Garg, K.
 - Constant number of goods now with Production poly time
 - Reduction from market with Production, PLC utilities to one with no production and PLC utilities with same set of equilibria (1-1 correspondance)

Overview of method

Step 1: Cell decomposition: Divide price space R^m₊ into small cells, either by hyperplanes or polynomial surfaces so that (intuitively), the "order" of the pieces in the PLC utilities is the same for all price vectors in the cell.

Overview of method

- Step 1: Cell decomposition: Divide price space R^m₊ into small cells, either by hyperplanes or polynomial surfaces so that (intuitively), the "order" of the pieces in the PLC utilities is the same for all price vectors in the cell.
- Step II : In each cell, either find a price that has a market clearing allocation, or certify that no such price exists. For this, one solves a system of linear/polynomial equations involving a constant number of variables.

 MUPUC = Increase in optimal utility when per unit increase in budget. (Simply slope divided by price of piece.)
