

# Information Design in Collective Decision Games

SEHER GUPTA

New York University

NMI Workshop, ISI Delhi, August 1st 2015

# Bayesian Persuasion in a (Voting) Game

- Consider a group of decision makers
  - Each votes on one of two alternatives
  - Outcome is decided by a voting rule

# Bayesian Persuasion in a (Voting) Game

- Consider a group of decision makers
  - Each votes on one of two alternatives
  - Outcome is decided by a voting rule
- Example – Board members of a company

# Bayesian Persuasion in a (Voting) Game

- Consider a group of decision makers
  - Each votes on one of two alternatives
  - Outcome is decided by a voting rule
- Example – Board members of a company
- Optimal choice depends on an *unknown* state of the world

# Bayesian Persuasion in a (Voting) Game

- Consider a group of decision makers
  - Each votes on one of two alternatives
  - Outcome is decided by a voting rule
- Example – Board members of a company
- Optimal choice depends on an *unknown* state of the world
- *Information designer*
  - payoff depends on the outcome
  - designs information structure to manipulate beliefs

# Bayesian Persuasion in a (Voting) Game

- Consider a group of decision makers
  - Each votes on one of two alternatives
  - Outcome is decided by a voting rule
- **Example** – Board members of a company
- Optimal choice depends on an *unknown* state of the world
- *Information designer*
  - payoff depends on the outcome
  - designs information structure to manipulate beliefs

# Bayesian Persuasion in a (Voting) Game

- Consider a group of decision makers
  - Each votes on one of two alternatives
  - Outcome is decided by a voting rule
- **Example** – Board members of a company
- Optimal choice depends on an *unknown* state of the world
- *Information designer*
  - payoff depends on the outcome
  - designs information structure to manipulate beliefs
- Question: **What is the optimal information structure?**

# Whom to persuade and How?

- Optimal Information Structure depends on:
  1. Set of **information structures** available to the designer:
    - Public Signals
    - Private Independent Signals
    - Arbitrarily Correlated Signals
  2. The Voting rule

# Whom to persuade and How?

- Optimal Information Structure depends on:
  1. Set of information structures available to the designer:
    - Public Signals
    - Private Independent Signals
    - Arbitrarily Correlated Signals
  2. The **Voting rule**
- Compare expected payoffs in equilibrium to analyze:
  - Which player will the designer target?
  - Will she include the most difficult to convince?
  - Which voting rule is least vulnerable to influence?

# Rules of the Game

- Two states of the world:  $\Theta = \{\theta_0, \theta_1\}$
- Two alternatives:  $\mathcal{X} = \{x_0, x_1\}$

# Rules of the Game

- Two states of the world:  $\Theta = \{\theta_0, \theta_1\}$
- Two alternatives:  $\mathcal{X} = \{x_0, x_1\}$
- Committee & Designer share a common prior:  $\psi \in \Delta(\Theta)$

# Rules of the Game

- Two states of the world:  $\Theta = \{\theta_0, \theta_1\}$
- Two alternatives:  $\mathcal{X} = \{x_0, x_1\}$
- Committee & Designer share a common prior:  $\psi \in \Delta(\Theta)$
- A **voting rule** is given. (# of votes required)

# Rules of the Game

- Two states of the world:  $\Theta = \{\theta_0, \theta_1\}$
- Two alternatives:  $\mathcal{X} = \{x_0, x_1\}$
- Committee & Designer share a common prior:  $\psi \in \Delta(\Theta)$
- A **voting rule** is given. (# of votes required)
- Designer chooses an information structure

# Rules of the Game

- Two states of the world:  $\Theta = \{\theta_0, \theta_1\}$
- Two alternatives:  $\mathcal{X} = \{x_0, x_1\}$
- Committee & Designer share a common prior:  $\psi \in \Delta(\Theta)$
- A **voting rule** is given. (# of votes required)
- Designer chooses an information structure
- State of the world is realized

# Rules of the Game

- Two states of the world:  $\Theta = \{\theta_0, \theta_1\}$
- Two alternatives:  $\mathcal{X} = \{x_0, x_1\}$
- Committee & Designer share a common prior:  $\psi \in \Delta(\Theta)$
- A **voting rule** is given. (# of votes required)
- Designer chooses an information structure
- State of the world is realized
- Players observe the signal; update beliefs
- They play a BNE of the induced game.

# The Committee

- Each member wants to match state & alternative
- *Differ* in cost of mismatch:

$$u_i(x, \theta) = \begin{cases} -q_i & \text{if } x = x_1, \theta = \theta_0 \\ -(1 - q_i) & \text{if } x = x_0, \theta = \theta_1 \\ 0 & \text{otherwise} \end{cases}$$

- $q_i \in (0, 1)$  is called the “**threshold of doubt**”.
- Higher  $q_i \Rightarrow$  more difficult to convince
- $i$  votes for  $x_1$  if belief on  $\theta_1 > q_i$

# The Information Designer

- Always wants the outcome to be  $x_1$
- Designs *information structure*  $\{T, \pi\}$ 
  1. Finite Realization Space:  $T$
  2. Conditional Distribution Functions:  $\pi : \Theta \rightarrow \Delta(T)$
- Only restriction on signals – *Bayes' Consistency*
- Solves the problem:

$$\begin{array}{ll} \max & \Pr(\text{outcome} = x_1) \\ \text{Subject To} & \textit{Incentive Constraints} \end{array}$$

# For the Talk Today

- Three Players:  $q_1 = 0.4, q_2 = 0.5, q_3 = 0.6$
- Common Prior:  $\psi_1 = 0.3$

# For the Talk Today

- Three Players:  $q_1 = 0.4$ ,  $q_2 = 0.5$ ,  $q_3 = 0.6$
- Common Prior:  $\psi_1 = 0.3$
- **Without any information:**
  - All players vote for  $x_0$
  - Designer's payoff = 0

# For the Talk Today

- Three Players:  $q_1 = 0.4$ ,  $q_2 = 0.5$ ,  $q_3 = 0.6$
- Common Prior:  $\psi_1 = 0.3$
- **Without any information:**
  - All players vote for  $x_0$
  - Designer's payoff = 0
- **Full Information:**
  - Players match state with alternative
  - Designer's expected payoff = 0.3

# For the Talk Today

- Three Players:  $q_1 = 0.4$ ,  $q_2 = 0.5$ ,  $q_3 = 0.6$
- Common Prior:  $\psi_1 = 0.3$
- **Without any information:**
  - All players vote for  $x_0$
  - Designer's payoff = 0
- **Full Information:**
  - Players match state with alternative
  - Designer's expected payoff = 0.3
- **Question:** *Can the designer do better?*

# Can the Designer Do Better?

Table : Designer's Expected Payoff

Information Structure	Majority Rule	Unanimity
No Information	0	0
Full Information	0.3	0.3
Public Signal		
Private Independent		
Correlated		

# Public Signal

- Same signal = same posterior
- But behavior *differs* because of *different*  $q_i$
- Reduces to **one** player problem
- $q_1 < q_2 < q_3 \Rightarrow$  Designer makes the marginal player indifferent.

# Optimal Information Structure

## Proposition

*Given a voting rule, the optimal information structure of the designer, with a public signal, is characterized by  $\{T, \pi\}$  with  $T = \{t_0, t_1\}$  and  $\pi : \Theta \rightarrow \Delta(T)$  is defined as:*

$$\begin{aligned} \pi(t_0|\theta_0) &= p_k & \text{and} & & \pi(t_0|\theta_1) &= 0 \\ \pi(t_1|\theta_0) &= 1 - p_k & \text{and} & & \pi(t_1|\theta_1) &= 1 \\ 1 - p_k &= & \frac{\psi_1}{\psi_0} & \left( \frac{1 - q_k}{q_k} \right) \end{aligned}$$

*where  $q_k$  is the threshold of doubt of  $k$ -th voter, and  $k$  is the number votes required for  $x_1$  be chosen as the outcome.*

# All in a Day's Work

Table : Designer's Expected Payoff

Information Structure	Majority Rule	Unanimity
No Information	0	0
Full Information	0.3	0.3
Public Signal	0.6	0.5
Private Independent		
Correlated		

# Private Information

- Signals are private, conditionally independent, identically distributed.
- No longer a one player problem!
- Two effects:
  1. Signals diverge – bad for designer
  2. **Strategic Voting** – (potentially) good for designer
- Being *pivotal* carries additional information.
- “Potentially” good – can infer a bad signal
- Is there some way to make strategic voting *good*?

# Go for the Easiest!

- To kill the bad signals: *convert all rules to unanimity*
- Designer targets the marginal player (easiest bunch to convince)

# Go for the Easiest!

- To kill the bad signals: *convert all rules to unanimity*
- Designer targets the marginal player (easiest bunch to convince)

Table : Designer's Expected Payoff

Information Structure	Majority Rule	Unanimity
No Information	0	0
• Full Information	0.3	0.3
Public Signal	0.6	0.5
Private Signal	0.6	0.5

# Designer as Mediator

- Designer can send arbitrarily **correlated signals**
- Think of the designer as making “recommendations”
- Optimizing over: distributions of *action* profiles

$$\sigma : \Theta \rightarrow \Delta(\mathcal{A})$$

- Solution concept – Bayes Correlated Equilibrium

# Main Results

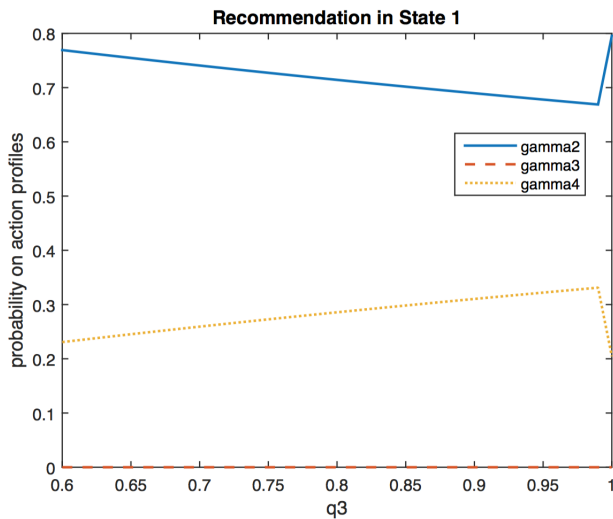

## Theorem (1)

*Under non-unanimous voting rules, using a public signal is sub-optimal for the designer.*

- There exist information structure with private correlated signals that give the designer a higher expected payoff.
- Designer does not target the marginal player!
- Calls upon the more-difficult-to-convince in the good state.

# Light, Shade and Perspective...

Figure : Illustrative Example

# Light, Shade and Perspective!

Figure : Illustrative Example

# Main Results

## Theorem (2)

*Under the unanimity rule, the optimal information structure of the designer is such that:*

$$\sigma(x_1, \dots, x_1 | \theta_1) = 1 \quad \text{and} \quad \sigma(x_1, \dots, x_1 | \theta_0) = \left( \frac{\psi_1}{\psi_0} \right) \left( \frac{1 - q_n}{q_n} \right)$$

*And the designer's expected utility is  $\frac{\psi_1}{q_n}$ .*

# United We Stand.

Table : Designer's Expected Payoff

Information Structure	Majority Rule	Unanimity
No Information	0	0
Full Information	0.3	0.3
Public Signal	0.6	0.5
Private Signal	0.6	0.5
Correlated Signals	0.6462	0.5

# That's all Folks!

- Two main **results**:
  1. Public Information is suboptimal for designer under non-unanimous voting rule
  2. Unanimity is least vulnerable to influence.
- Two main **contributions**:
  1. Bayesian Persuasion with Strategic interaction
  2. Private and Correlated Signals
