Coding the Golden Code

*D. Champion, J.-C.
Belfiore, G. Rekaya and
E. Viterbo*

Introduction

*Outer-Coded Space-Time
Block Codes*

*Code construction a la
Ungerboeck*

The Golden Code

A quaternary partition

*How to increase the
coding gain?*

*The Golden Leech Lattice
 $\mathcal{G}_{\Lambda_{24}}$*

*A trellis-coded Golden
modulation*

Conclusion

- In standards for which a space-time code solution is defined (it can be the **Alamouti code**, the **Spatial Multiplexing (VBLAST)** or the **Golden Code**), a binary outer code is concatenated (convolutional code, LDPC code, turbo-code).
- These standards are
 - IEEE 802.11n (WiFi)
 - IEEE 802.16e (WiMax and WiBro)
 - 3GPP (3G systems)
- Concatenating a binary outer code is quite easy to do for the Alamouti code and the S.M.
- But we do not know how to correctly label the Golden Code
- This talk will give a first answer to this question, but it will also ask some new questions and enlight new problems.

Coding the Golden Code

*D. Champion, J.-C.
Belfiore, G. Rekaya and
E. Viterbo*

Introduction

*Outer-Coded Space-Time
Block Codes*

*Code construction a la
Ungerboeck*

The Golden Code

A quaternary partition

Introduction

Outer-Coded Space-Time Block Codes

The quasi static fading channel
The inner/outer codes

Code construction a la Ungerboeck

The Golden Code

A quaternary partition

How to increase the coding gain?

The Golden Leech Lattice $\mathcal{G}\Lambda_{24}$

A trellis-coded Golden modulation

Conclusion

Figure: The Channel Model

- Received signal

$$\mathbf{Y}_{n_r \times T} = \mathbf{H}_{n_r \times n_t} \cdot \mathbf{X}_{n_t \times T} + \mathbf{W}_{n_r \times T} \quad (1)$$

with \mathbf{H} perfectly known at the receiver.

- \mathbf{H} is assumed constant during the transmission of one codeword.

Coding the Golden Code

D. Champion, J.-C. Belfiore, G. Rekaya and E. Viterbo

Introduction

Outer-Coded Space-Time Block Codes

The quasi static fading channel
The inner/outer codes

Code construction a la Ungerboeck

The Golden Code

A quaternary partition

How to increase the coding gain?

The Golden Leech Lattice $\mathcal{E}\Lambda_{24}$

A trellis-coded Golden modulation

Conclusion

- $\mathbf{X}_i - \mathbf{X}_j$ is the difference between two codewords.
- Some common claims
 - ① **Rank Criterion:** The minimum rank of the difference of any pair of non equal codewords should be maximized
 - ② **Determinant criterion:** Maximize (only for high SNR)

$$\min_{\substack{\mathbf{X}_i \neq \mathbf{X}_j \\ \mathbf{X}_i, \mathbf{X}_j \in \mathcal{C}}} \det \left((\mathbf{X}_i - \mathbf{X}_j) (\mathbf{X}_i - \mathbf{X}_j)^T \right)$$

- ③ **Trace criterion:** Maximize (only for low SNR)

$$\min_{\substack{\mathbf{X}_i \neq \mathbf{X}_j \\ \mathbf{X}_i, \mathbf{X}_j \in \mathcal{C}}} \text{Tr} \left((\mathbf{X}_i - \mathbf{X}_j) (\mathbf{X}_i - \mathbf{X}_j)^T \right)$$

- We will satisfy all these criteria, but some surprises could happen

Conclusion

- Take an element with norm 4. Obviously, 2 is OK. $2\mathbb{Z}[i]$ is a principal ideal of norm 4.

- Form the quotient $\mathbb{Z}[i]/2\mathbb{Z}[i]$. This quotient ring has cardinality 4 (the norm of the ideal $2\mathbb{Z}[i]$) and the class representatives are $0, 1, i, 1+i$.

- We have in fact

$$\mathbb{Z}[i]/2\mathbb{Z}[i] \cong \mathbb{F}_2 \oplus u \cdot \mathbb{F}_2 \quad u^2 = 0$$

by associating u to the class whose representative is $1+i$.

- Check that $(1+i)^2 = 2i$ is a multiple of 2
- Now replace $\mathbb{Z}[i]$ by the Golden Code ...
 - Things are becoming (much) less obvious

by associating u to the class whose representative is $1+i$.

- Check that $(1+i)^2 = 2i$ is a multiple of 2
- Now replace $\mathbb{Z}[i]$ by the Golden Code ...
 - Things are becoming (much) less obvious

Criterion for partition

We propose to partition the Golden Code in order to have a chain with increasing minimum determinant and (perhaps) increasing minimum Euclidean distance. Note that the norm is replaced here by the reduced norm.

Conclusion

How to find the partitioning ideal?

What we are looking for..

An ideal whose norm is a power of 2 (Communication engineers want to send bits and not trits or everything else). This power must be as small as possible.

- We have adjoined to \mathbb{K} the element e such that $e^2 = i$.

Methodology

Construct $L \triangleq \mathbb{K}(\sqrt{i}) = \mathbb{Q}(\zeta_8, \theta)$ and look for ideals whose norms are a power of 2.

- The smallest power of 2 which works is 4 corresponding to a principal ideal generated by

$$(1 - \theta)(i + \zeta_8)$$

- Replace ζ_8 by e but be careful with the non commutativity!

Introduction

Outer-Coded Space-Time Block Codes

Code construction a la Ungerboeck

The Golden Code

A quaternary partition

How to increase the coding gain?

The Golden Leech Lattice $\mathcal{G}\Lambda_{24}$

A trellis-coded Golden modulation

Code and simulations

Conclusion

- With a 4-state code, we can achieve 1.5dB gain
- With a 16-state code, it is possible to achieve 3dB gain

Convolutional code and bit labelling

Bit c_0 is set to 0.

General Coding gain

In general, to achieve 1.5 rdB asymptotic gain compared to the Golden code, we need a trellis with 2^{2r} state.

Coding the Golden Code

The Golden Code

A quaternary partition

How to increase the coding gain?

The Golden Leech Lattice \mathcal{G}_{24}

A trellis-coded Golden modulation

Code and simulations

Conclusion

Simulation results

- Lots of unsolved problems (roles of Euclidean distances and determinants, link with capacity approaching codes, new mappings, ...)
- But this first attempt gives encouraging results
- Generalization to other division algebras (perfect space-time block codes)
